Whole-body nitrogen balance and colonic segmental motility in the rat: effect of fasting and feeding. The present study examined the relationships between whole-body nitrogen balance and colonic segmental motility in the rat. Colonic motility was measured using perfused colon segments, and whole-body nitrogen balance was determined during 48-h fasts and 48-h refeeds. Plasma amino acid concentrations were measured by a chromatographic method. Fasting resulted in a significant reduction of whole-body nitrogen balance (P less than 0.05), increased fecal output (P less than 0.001), and induced a biphasic motility profile. Mean colonic motility decreased in the fasted animals, whereas the amplitude of colonic contractions and motility index increased (P less than 0.001). 77a5ca646e
