The Activation of Peroxisome Proliferator-Activated Receptors (PPAR) by Synthetic Organsulfonamides (SOSAs) and Their Biological Significance. The advent of thiazolidinedione antidiabetics stimulated the interest in peroxisome proliferator-activated receptors (PPAR), which are ligand-activated nuclear receptors that function as transcription factors to regulate the expression of their target genes that control the basic biological functions of cells, including energy metabolism, inflammation, cardiovascular development and cancers. The first member of the PPARs, PPAR- $\alpha$ , was identified in 1993 and was demonstrated to be the receptor of peroxisome proliferators. Members of the PPARs, including PPAR- $\alpha$ , - $\beta$ , and - $\delta$  were identified on the basis of pharmacological properties, genes, and
